

BAMSurgeon: Methods for spike-in mutations on BAM files

Adam D. Ewing (adam.ewing@mater.uq.edu.au)

May 22, 2014

1 Introduction

1.1 Software Dependencies

BAMSurgeon requires the following software packages be available:

1. samtools/wgsim/tabix (<http://samtools.sourceforge.net/>)
2. pysam (<http://code.google.com/p/pysam/> or `pip install pysam`)
3. bwa (<http://bio-bwa.sourceforge.net/>)
4. velvet (<http://www.ebi.ac.uk/~zerbino/velvet/>)
5. exonerate (<http://www.ebi.ac.uk/~guy/exonerate/>)
6. picard (<http://picard.sourceforge.net/>)

1.2 How to (f|m)ake a tumour

One of the primary use cases for BAMSurgeon is to test somatic mutation calling methods, so we have provided an outline of how this can be accomplished (Fig 1). Suggestions for improvements to the process are welcome. There are three stages to this process:

1. Preprocessing (BAM selection and splitting)
2. Mutating (selecting mutation sites, running BAMSurgeon, generating “truth” VCFs)
3. Postprocessing (BAM repair, GATK IndelRealigner, BQSR)

1. Preprocessing TODO

2. Mutating TODO

3. Postprocessing TODO

1.3 Known bugs and limitations

BAMSurgeon is under rapid development driven by suggesting and bug reports from the mutation calling community.

2 Adding SNVs to existing BAM alignments (addsnv)

2.1 Usage

```
usage: addsnv.py [-h] -v VARFILENAME -f BAMFILENAME -r REFFASTA -o OUTBAMFILE
                  [-s SNVFRAC] [-m MUTFRAC] [-n NUMSNVS] [-c CNVFILE]
                  [-d COVERDIFF] [-p PROCS] [--samtofastq SAMTOFASTQ]
                  [--mindepth MINDEPTH] [--nomut] [--det] [--force] [--single]
                  [--maxopen MAXOPEN] [--requirepaired] [--skipmerge]
                  [--bwamem]
```

addsnv adds SNVs to reads, outputs modified reads as .bam along with mates

optional arguments:

```
-h, --help                show this help message and exit
-v VARFILENAME, --varfile VARFILENAME
                           Target regions to try and add a SNV, as BED
-f BAMFILENAME, --bamfile BAMFILENAME
                           sam/bam file from which to obtain reads
-r REFFASTA, --reference REFFASTA
                           reference genome, fasta indexed with bwa index -a
                           stdsw_and_samtools faidx
-o OUTBAMFILE, --outbam OUTBAMFILE
                           .bam file name for output
-s SNVFRAC, --snvfrac SNVFRAC
                           maximum allowable linked SNP MAF (for avoiding
                           haplotypes) (default = 1)
-m MUTFRAC, --mutfrac MUTFRAC
                           allelic fraction at which to make SNVs (default = 0.5)
-n NUMSNVS, --numsnvs NUMSNVS
                           maximum number of mutations to try (default: entire
                           input)
-c CNVFILE, --cnvfile CNVFILE
                           tabix-indexed list of genome-wide absolute copy number
                           values (e.g. 2 alleles = no change)
-d COVERDIFF, --coverdiff COVERDIFF
                           allow difference in input and output coverage
                           (default=0.9)
-p PROCS, --procs PROCS
                           split into multiple processes (default=1)
--samtofastq SAMTOFASTQ
                           path to picard SamToFastq.jar
--mindepth MINDEPTH      minimum read depth to make mutation
--minmutreads MINMUTREADS
                           minimum number of mutated reads to output per site
--avoidreads AVOIDREADS
                           file of read names to avoid (mutations will be skipped
                           if overlap)
```

<code>--nomut</code>	dry run
<code>--det</code>	deterministic base changes: make transitions only
<code>--force</code>	force mutation to happen regardless of nearby SNP or low coverage
<code>--single</code>	input BAM is single-ended (default is paired-end)
<code>--maxopen MAXOPEN</code>	maximum number of open files during merge (default 1000)
<code>--requirepaired</code>	skip mutations if unpaired reads are present
<code>--skipmerge</code>	final output is tmp file to be merged
<code>--bwamem</code>	realignment with BWA MEM (instead of backtrack)

2.2 Description

Single nucleotide changes are introduced to an existing BAM alignment using `addsnv.py` as outlined in Figure 2. Input consists of a list of locations where SNVs will be made, a target BAM alignment, and a reference genome indexed using `bwa` (preferably the same genome used to align the reads in the BAM file).

2.3 Input

Mutation input (-v/-varfile) Input to `addsnv.py` (-v/-varfile) is BED-3 format plus an extra optional column for the desired variant allele fraction (VAF). The default VAF is specified via -m/-mutfrac. For example:

```
22 34166720 34166720 0.25
22 33908770 33908770 0.15
22 33714964 33714964 0.5
22 33769483 33769483 0.75
22 33958087 33958087 0.01
22 34264774 34264774 0.25
22 33702084 33702084 0.2
22 34141184 34141184
22 33926586 33926586
22 33943910 33943920
```

The above input will cause `addsnv` to attempt 10 SNVs at the specified locations, using the VAF specified in the fourth column if available, otherwise defaulting to 0.5 or whatever is specified by -m/-mutfrac (e.g. the last three lines). Note that the positions in the last input line define a region 10bp wide rather than a specific position as in the first 9 lines. When specified this way, `addsnv` will choose one of the 10 possible positions at random.

BAM Alignment input (-f/-bamfile) BAMs ideally should adhere to SAM specification i.e. they should validate via `picard's ValidateSamFile`. BAMs should be sorted in coordinate order and indexed. BAMs should consist either of entirely paired-end reads or entirely single-end (fragment) reads using the `--single` option, mixing paired and single reads yields unpredictable results. Currently, `bwa backtrack` (`bwa aln`) and `bwa mem` are supported, although it should be straightforward enough to add further aligners through modification of the `remap-paired` function. In practice we have been able to spike mutations into RNA-seq MapSplice BAMs, for instance.

Reference genome (-r/-reference) The reference genome should be the **same as that used to create the target BAM file**, specifically the chromosome names and lengths in the reference FASTA must be the same as in the BAM header. The reference must be indexed for bwa (`bwa index`) and indexed with samtools (`samtools faidx`).

Avoiding existing SNPs with -s/-snpprac (optional, default=1.0) In an attempt to preserve haplotype structure and avoid confusion by spiking mutations on top of existing heterozygous alleles, the -s/-snpprac cutoff may be useful. For a selected mutation site S and specified cutoff f starting from the leftmost base L of the leftmost read containing S and ending at the rightmost base R of the rightmost read containing S , the minor allele frequency M for every intervening base is calculated for every base in the interval $[L, R]$. If $M < f$ for all bases in $[L, R]$ the mutation at S is allowed, and skipped otherwise. Note, do not confuse this with -m/-mutfrac, which is the target variant allele frequency for mutations unless overridden in the mutation input file. By default this function is turned off (threshold minor allele frequency set to 1.0). Setting this too low can yield few successful mutations as sequence errors will inhibit successful spike-in, we recommend a setting of 0.1 for Illumina GA/HiSeq reads.

CNV file (-c/-cnvfile) (optional) It is possible to simulate adding mutations to a single haplotype for copy-number variant regions. For example, if a region has absolute copy number 3 (instead of 2), a mutation into one haplotype should have an apparent VAF of roughly 0.33 instead of 0.5. This optional file should be in BED-3 format plus a fourth column representing the absolute copy number for the region defined by the chromosome/contig, start, and end fields. The genome is assumed to be diploid thus an absolute copy number of 2 will not adjust the variant allele fractions. Absolute copy numbers below 2 will adjust VAFs higher and absolute copy numbers above 2 will adjust VAFs correspondingly lower.

Additional options

- -d/-coverdiff : threshold on output coverage divided by input coverage for mutation sites. Mutations can cause alignments to change, if this is undesired set this high, if this is part of the fun, set this low.
- -p/-procs : BAMSurgeon programs currently spawn a new process for each spikein, to speed things along the processes can be run concurrently with the number of simultaneous jobs set by this parameter.
- -samtofastq : path to SamToFastq.jar provided by picard tools, this is required for the -bwamem option
- -mindepth : minimum depth at sites for mutations, sites with fewer reads in pileup column will be dropped. Default is 5 reads.
- -minmutreads : minimum number of mutated reads per site. If this level of coverage cannot be obtained, mutations will be dropped.
- -avoidreads : addsnv and addindel can be passed a list of read names to avoid when making mutations. Any sites selected that overlap these reads will be dropped. This feature exists as a means to ensure mutations across multiple runs do not overlap.

- `-force` : force the addition of a mutation even if it fails thresholds set by `-mindepth` and `-c/-coverdiff`. Not recommended for most use cases.
- `-single` : covered above, assume reads are single-end (i.e. fragment reads).
- `-maxopen` : set the maximum number of open files (check your system limit with `ulimit -a`)
- `-requirepaired` : drop mutations where a paired end in the region cannot be located. However, it is probably better to correct the problem in the BAM file than to resort to using this option.
- `-skipmerge` : instead of replacing the mutated and realigned reads back into the original BAM, which is normally the final step, leave the addsnv.
- `-bwamem` : realign reads using bwa mem. The target BAM file should have also been aligned using bwa mem if this option is used.
- options not listed here are either brand new and the manual has not been updated as yet, or they are there for debugging and will be removed in the future.

3 Adding INDELs to existing BAM alignments (addindel)

3.1 Usage

```
usage: addindel.py [-h] -v VARFILENAME -f BAMFILENAME -r REFFASTA -o
                  OUTBAMFILE [-s SNVFRAC] [-m MUTFRAC] [-n NUMSNVS]
                  [-c CNVFILE] [-d COVERDIFF] [-p PROCS]
                  [--samtofastq SAMTOFASTQ] [--mindepth MINDEPTH] [--nomut]
                  [--det] [--force] [--single] [--maxopen MAXOPEN]
                  [--requirepaired] [--bwamem] [--skipmerge]
```

adds SNVs to reads, outputs modified reads as .bam along with mates

optional arguments:

```
-h, --help                show this help message and exit
-v VARFILENAME, --varfile VARFILENAME
                          Target regions to try and add a SNV, as BED
-f BAMFILENAME, --bamfile BAMFILENAME
                          sam/bam file from which to obtain reads
-r REFFASTA, --reference REFFASTA
                          reference genome, fasta indexed with bwa index -a
                          stdsw_and_ samtools faidx
-o OUTBAMFILE, --outbam OUTBAMFILE
                          .bam file name for output
-s SNVFRAC, --snvfrac SNVFRAC
                          maximum allowable linked SNP MAF (for avoiding
                          haplotypes) (default = 1)
-m MUTFRAC, --mutfrac MUTFRAC
                          allelic fraction at which to make SNVs (default = 0.5)
-n NUMSNVS, --numsnvs NUMSNVS
                          maximum number of mutations to try (default: entire
```

```

        input)
-c CNVFILE, --cnvfile CNVFILE
        tabix-indexed list of genome-wide absolute copy number
        values (e.g. 2 alleles = no change)
-d COVERDIFF, --coverdiff COVERDIFF
        allow difference in input and output coverage
        (default=0.1)
-p PROCS, --procs PROCS
        split into multiple processes (default=1)
--samtofastq SAMTOFASTQ
        path to picard SamToFastq.jar
--mindepth MINDEPTH
        minimum read depth to make mutation
--minmutreads MINMUTREADS
        minimum number of mutated reads to output per site
--avoidreads AVOIDREADS
        file of read names to avoid (mutations will be skipped
        if overlap)

--nomut
        dry run
--det
        deterministic base changes: make transitions only
--force
        force mutation to happen regardless of nearby SNP or
        low coverage
--single
        input BAM is single-ended (default is paired-end)
--maxopen MAXOPEN
        maximum number of open files during merge (default
        1000)
--requirepaired
        skip mutations if unpaired reads are present
--bwamem
        realignment with BWA MEM (instead of backtrack)
--skipmerge
        final output is tmp file to be merged

```

3.2 Description

Short insertions and deletions (commonly referred to as INDELs) can be added to BAM files using `addindel.py`. The options are essentially the same as for `addsnv.py`, but the syntax of the input file is slightly different:

```

22 33694303 33694304 0.50 INS ATGGC
22 33815273 33815274 0.25 INS CG
22 33920490 33920491 0.33 INS ATTTGCTTAGCTGAGGGCTTAGGCTTAGCATGCGTA
22 33944542 33944543 0.50 DEL
22 34006643 34006653 0.50 DEL
22 33958087 33958090 0.40 DEL

```

The first four columns are the same as for `addsnv.py` input but the fourth column (VAF) is mandatory. The fifth column must be either 'INS' or 'DEL' (for insertion or deletion). For insertions there must be a sixth column specifying the sequence to be inserted at the position indicated in the second column (the position in the third column does not matter for insertions). In the above example, the first three columns direct `addindel.py` to (1) add an insertion of "ATGGC"

at chromosome 22 position 33694303 with 50% VAF, (2) add an insertion of “CG” at position 338152273 with 25% VAF, and (3) add an insertion of “ATTTGC...” with 33% VAF.

For deletions, the sequence from the start to the end (columns two and three) is deleted. Lines 4,5, and 6 above indicate deletions of 1 bp, 10bp, and 3 bp, respectively.

4 Adding SVs to existing BAM alignments (addsv.py)

4.1 Usage

```
usage: addsv.py [-h] -v VARFILENAME -f BAMFILENAME -r REFFASTA -o OUTBAMFILE
               [-l MAXLIBSIZE] [-k KMERSIZE] [-s SVFRAC]
               [--maxctglen MAXCTGLEN] [-n MAXMUTS] [-c CNVFILE]
               [--ismean ISMEAN] [--issd ISSD] [-p PROCS] [--inslib INSLIB]
               [--delay DELAY] [--nomut] [--noremap] [--noref] [--recycle]
               [--bwamem] [--skipmerge]
```

adds SNVs to reads, outputs modified reads as .bam along with mates

optional arguments:

```
-h, --help                show this help message and exit
-v VARFILENAME, --varfile VARFILENAME
                           whitespace-delimited target regions to try and add a
                           SNV: chrom,start,stop,action,seqfile (if
                           insertion),TSDlength (if insertion)
-f BAMFILENAME, --sambamfile BAMFILENAME
                           sam/bam file from which to obtain reads
-r REFFASTA, --reference REFFASTA
                           reference genome, fasta indexed with bwa index -a
                           stdsw_and_ samtools faidx
-o OUTBAMFILE, --outbam OUTBAMFILE
                           .bam file name for output
-l MAXLIBSIZE, --maxlibsize MAXLIBSIZE
                           maximum fragment length of seq. library
-k KMERSIZE, --kmer KMERSIZE
                           kmer size for assembly (default = 31)
-s SVFRAC, --svfrac SVFRAC
                           allele fraction of variant (default = 1.0)
--maxctglen MAXCTGLEN
                           maximum contig length for assembly - can increase if
                           velvet is compiled with LONGSEQUENCES
-n MAXMUTS
                           maximum number of mutations to make
-c CNVFILE, --cnvfile CNVFILE
                           tabix-indexed list of genome-wide absolute copy number
                           values (e.g. 2 alleles = no change)
--ismean ISMEAN
                           mean insert size (default = estimate from region)
--issd ISSD
                           insert size standard deviation (default = estimate
                           from region)
-p PROCS, --procs PROCS
```

	split into multiple processes (default=1)
--inslib INSLIB	FASTA file containing library of possible insertions, use INS RND instead of INS filename to pick one
--delay DELAY	time delay between jobs (try to avoid thrashing disks)
--nomut	dry run
--noremap	dry run
--noref	do not perform reference based assembly
--recycle	
--bwamem	realign with bwa mem (original should be aligned with mem as well!)
--skipmerge	

4.2 Description

Larger structural variants (insertions, deletions, duplications, inversions, and compound rearrangements) are added to existing BAM alignments using `addsv.py` as described in Figure 3. Input consists of a list of regions where SVs will be made along with a specification of each variant, and as with `addsnv` and `addindel`, a target BAM alignment, and a reference genome indexed using `bwa` are required.

4.3 Input

The input mutation list consists of four columns: chromosome, start of region, end of region, and a controlled-vocabulary description of the mutation. A mutation will not be made if the largest contig obtained from local assembly of the specified region is less than 3 times the maximum expected library size (specified by `-l/--maxlibsize`). The mutation description starts with either `INS`, `DEL`, `DUP`, or `INV` for insertion, deletion, duplication, and inversion, respectively and is followed by mutation-specific options. An example follows.

```
22 33871043 33884754 DEL 0.9
22 33971043 33984754 INS myseq.fa
22 34071043 34084754 INV
22 34171043 34184754 INS ACTATCGTGGGCTTATGGCTTAGCATTACGGTTATTTTGCCTGATCGCGGGGGCTACATCATTTCATG
22 34271043 34284754 DUP 3
22 34371043 34384754 INS RND
```

For insertions, `INS` should be followed by either a FASTA file containing the sequence to be inserted, by the nucleotide sequence itself, or by `RND` if a library of potential insertion sequences is passed in FASTA format via the `-inslib` option. For example, `INS ATG` would insert the sequence ‘‘ATG’’ in the middle of the largest contig obtained from the specified region, while `INS LINE1.fa` would insert the sequence in the FASTA-formatted file `LINE1.fa` into the largest contig. For deletions, `DEL` should be followed by the fraction of the largest contig to be deleted, where 1.0 indicates a deletion of the largest assembled region minus one library length on each end. e.g. `DEL 0.5`. Inversions (`INV`) have no further options - the region inside the largest contig will be inverted. Duplications (`DUP`) have one optional parameter, an integer specifying the number of times the sequence of the largest contig should be duplicated, e.g. `DUP 2` specifies the region is duplicated twice. In general, we recommend that short insertions and deletions (those shorter than

one read length) be created with `addindel.py` instead of `addsv.py` as `addindel.py` does not require reconstruction of the region through sequence assembly and is thus less error-prone.

Compound variants are also possible by chaining a number of mutations together in a comma-delimited list, e.g. `DUP 1, DEL 0.5, INS AAATCC, INV` would duplicate the region inside the largest contig once, delete half the width of the region, insert the sequence `AAATCC`, and invert the region. Good luck!

4.4 Output

Where mutations add sequence (e.g. duplications), new reads are created that will be added to the original BAM, and where mutations remove sequence (e.g. deletions) those reads are marked as excluded (excluded read names are recorded in the file specified by `-x/--excluded`). Excluded reads are not carried over from the original BAM to the mutated BAM, creating the copy number effect associated with deletion.

Output consists of a BAM file containing the spike-in mutations and a directory of log files describing which bases were changed in which reads (one log per mutation) and the local assemblies for each region where a mutation was made. Currently, the directory containing output logs for SV spike-ins can be transformed into VCF format using the script `makevcf_sv.py` in the `etc/` subdirectory. The spike-in process may be done concurrently through the use of the `-p/--procs` option. Here are some extended descriptions for additional options not mentioned yet:

- `-s/--snvfrac` : equivalent to `-m/--mutfrac` for `addindel.py` and `addsnv.py` (will fix)
- `-k/--kmer` : kmer size to be fed to velvet, which is used for assembly
- `-n` : only attempt this many mutations
- `-ismean/--issd` : the mean and standard deviation of the library size should be estimated from the original bam and specified through these arguments. This can be accomplished a number of ways, I suggest `CollectInsertSizeMetrics` from the picard tools.
- `-inslib` : a FASTA file can be specified and insertions can be tagged with RND instead of a sequence or file. If this is done, a sequence will be chosen at random from the FASTA file specified by `-inslib` and inserted.
- `-bwamem` : as with other scripts, use bwa mem instead of the default which is bwa backtrack
- `-skipmerge` : same meaning as for `addsnv/addindel`

Figure 1: Method for adding SNVs to existing BAM alignments. Starting with the original BAM alignment (a) and a list of positions (b), reads overlapping the chosen positions are selected the target base change is made (c). Altered reads are re-mapped the the reference genome using bwa, and the modified, realigned reads replace the unmodified versions in the original BAM (d).

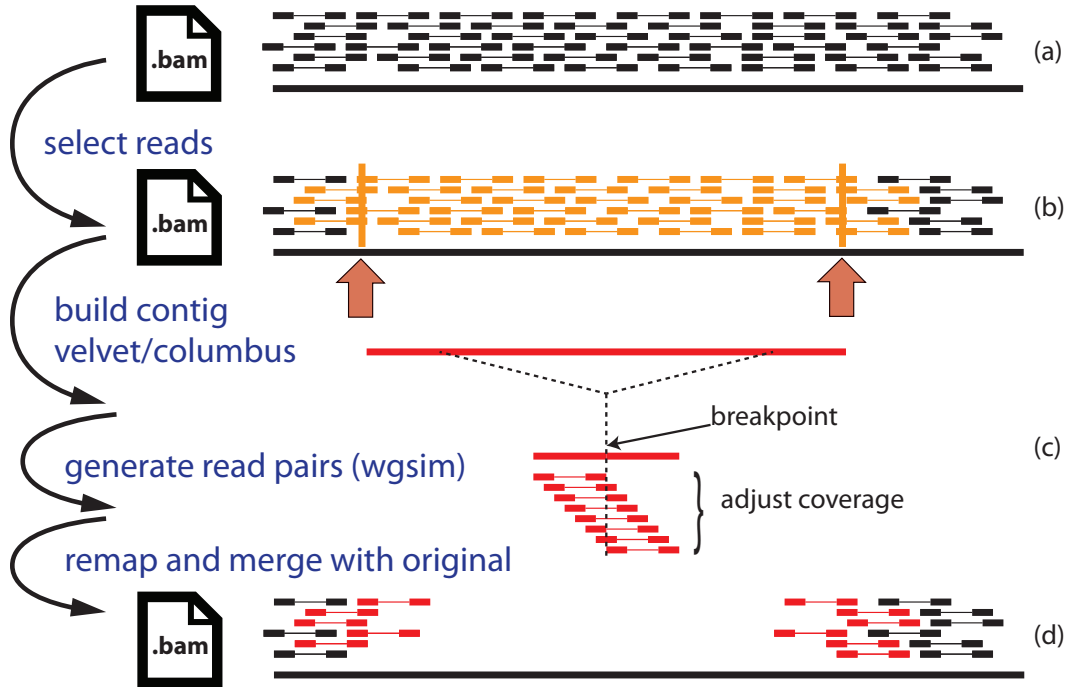

Figure 2: Method for adding multi-nucleotide variants (indels and SVs) to existing BAMs: deletion example. Starting with the original BAM alignment (a) regions, e.g. (b), are assembled using Velvet/Columbus (<http://www.ebi.ac.uk/zerbino/velvet/>) and the desired mutation(s) are created in the largest contig. Read coverage is simulated over the contig using wgsim (<https://github.com/lh3/wgsim>, also included with samtools) with parameters `-e 0 -r 0 -R 0` to suppress additional mutations, other parameters are set based on the input BAM and desired coverage. Simulated coverage is scaled based on whether the mutation adds sequence (duplication) or removes sequence (deletions), and replaced into the original BAM while excluded reads are removed from the original BAM (d).

5 Testing

The `test/` directory contains scripts useful for testing bamsurgeon installations, one for SNVs and one for SVs.

5.1 Testing addsnv.py

The script `test/test_snv.sh` may be run with no parameters to display a usage statement:

```
usage: ./test_snv.sh <number of SNPs> <number of threads> <reference indexed with bwa index>
```

The number of SNPs can be up to 100 and are selected from the file `test_data/random_snvs.txt`, number of threads must be specified, use 1 to run on a single core, and the final argument must be a path to a human genome (GRCh37) reference indexed with `bwa index -a bwtsv`. The reference **should not** use the 'chr' prefix on the chromosome names.

5.2 Testing addindel.py

The script `test/test_sv.sh` may be run with no parameters to display a usage statement:

usage: ./test_indel.sh <number of threads> <reference indexed with bwa index>

5.3 Testing addsv.py

The script test/test_sv.sh may be run with no parameters to display a usage statement:

usage: ./test_sv.sh <number of threads> <reference indexed with bwa index>

6 Other Considerations

6.1 System Requirements

For each process (specified by -p/-procs) add*.py will require 4GB RAM. So for 8 concurrent mutation processes, you should have 32GB RAM. System requirements may decrease in the future as we find ways to improve efficiency.

6.2 Alignments

Reads should be re-aligned using the same aligner and parameters as were used to create the original BAM file. By default, bamsurgeon assumes alignments were performed using bwa aln with parameters -q 5 -l 32 -k 3 -o 1. The specific parameters are not currently specifiable on the command line but may be altered through modification of the functions `remap_paired` (for paired reads) or `remap_single`.

7 Acknowledgements

We would like to thank everyone who has submitted a pull request or bug report through github, the synapse forums for the DREAM Somatic Mutation Calling challenge, or by other means.
